# ABSTRACT

The laminar length of a submerged jet of a non-Newtonian fluid is experimentally investigated. A flow visualization technique, which makes use of the birefringent property of the fluid and a circular polariscope, is employed to measure the laminar length. The experimental facility is also used as a "falling head" capillary viscometer. The laminar length data and the viscosity data are taken simultaneously.

Fluids of two different concentrations are studied. The results indicate that the concentration, hence the non-Newtonian nature of the fluid, has no influence on the laminar length of the jet for  $600 < Re < 1100$ . In the Reynolds number range of 50 to 200 the laminar length is affected by the viscous properties of the fluid. The results also indicate that there is not much difference in the laminar length of a Newtonian and non-Newtonian jet for  $600 < Re < 1100$ . The viscosity obtained from the present test facility is found to agree reasonably well with that obtained using a standard rotary viscometer.

#### ACKNOWLEDGEMENTS

The author wishes to express his deep and sincere gratitude to Drs. G.W. Rankin and K. Sridhar for their excellent guidance, unceasing help and generous aid during this study.

Thanks are due to Dr. Dekee for allowing the Rhegmat viscometer to be available for the present study. The valuable suggestions of Dr. North, Dr. Dekee and Dr. McDonald are greatly acknowledged.

Technical assistance rendered by Mr. R. Tattersall in constructing the test facility is greatly acknowledged. Thanks are also due to Mrs. Carr for typing the manuscript.

The study was financially supported by Natural Sciences and Engineering Research Council of Canada through Grant Numbers A-2190 and A-1403.

## CHAPTER I

### INTRODUCTION

#### 1.1 Subject of Study

A submerged jet is formed when a fluid exits through a tube into a volume of the same fluid. In the present study the flow is fully developed and laminar at the tube exit. The jet continues to be laminar for some distance downstream of the tube exit. Beyond this distance the jet can become unstable causing transition to turbulent flow. The distance from the exit plane of the tube to the laminar to turbulent transition point is called the natural laminar length or simply laminar length. Figure 1.1 illustrates the various regions of a laminar-turbulent submerged jet.

Depending upon the Reynolds number in the tube, the jet may be any one of the following types:

- (a) Fully laminar jet
- (b) Laminar-turbulent jet
- (c) Fully turbulent jet.

The present work is concerned with laminar-turbulent and fully laminar jets. In the case of a fully laminar jet the laminar length is the length after which the jet diffuses completely into the surrounding fluid without becoming turbulent.

This thesis presents an experimental investigation of the natural laminar length of an axisymmetric, submerged, non-Newtonian jet. Of particular interest is the effect that the concentration of the non-Newtonian fluid has on the laminar length. The non-

Newtonian fluid is prepared by mixing an organic dye powder in distilled water. The dye powder is commercially known as Milling Yellow and is supplied by Keystone Aniline & Chemicals Co., Chicago, Illinois, U.S.A. A flow visualization technique, which makes use of the birefringent characteristic of the fluid, is employed to measure the laminar length of the jet. The experimental facility allows simultaneous measurement of the viscosity of the fluid and the laminar length of the jet. The viscosity is determined using the test facility as a "falling head" capillary viscometer in conjunction with a non-linear parameter estimation technique. Laminar length measurements are taken using a displacement transducer and digital read-out unit.

### 1.2 Significance

One area in which the submerged jet finds an application is in the operation of fluidic devices such as the turbulence amplifier. Both a laminar-turbulent and fully laminar jet are essential for the proper functioning of this device. For a successful design, information concerning the stability of the jet is required. A number of current or potential applications of the turbulence amplifier require operation with non-Newtonian fluids. Most of the fluids encountered in the chemical industry, petroleum industry, food processing plants and many biological fluids are non-Newtonian in nature. It is speculated, in the literature, that the non-Newtonian behaviour of the fluid may affect the laminar length of the jet and hence the operation of the turbulence amplifier. Information on the variation of laminar length with Reynolds number will help the designer to determine the feasibility

and proper operation of such devices. The present study provides this information.

Research papers on non-Newtonian jets, particularly those concerning experimental investigations, are limited in number. It is expected that the results of the present study will be of some help to researchers attempting to achieve a basic understanding of non-Newtonian jets.

### 1.3 Aims

The main objectives of the present study are

(a) to investigate the variation of the laminar length of a submerged, axisymmetric jet of non-Newtonian fluid as a function of Reynolds number and its concentration, by using a birefringent flow visualization technique and also to make comparisons with previous Newtonian studies.

(b) to obtain the variation of the viscosity of the non-Newtonian fluid with shear rate, concurrently with the laminar length measurements using a non-linear parameter estimation technique in conjunction with a "falling head" capillary viscometer procedure.

## CHAPTER II

### LITERATURE SURVEY

The literature covered in this survey can be grouped into three major areas. These are:

- (a) Non-Newtonian jets
- (b) Laminar length measurements
- (c) Characteristics of the fluid selected.

Each one is considered separately in what follows.

#### 2.1 Non-Newtonian Jets

Most of the literature covered in this survey is concerned with solving the momentum equation to obtain the jet velocity profiles. Although this topic is not directly related to the present investigation it helps one to understand the basic behaviour of non-Newtonian jets. The literature cited below is predominantly concerned with laminar, incompressible, isothermal, submerged, non-Newtonian jets of a pseudo-plastic fluid.

Kapur (7) obtained a closed form similarity solution for the case of a two dimensional, incompressible jet of a power law fluid based on boundary layer assumptions. The closed form solution contained implicit functions for velocities and was expressed in terms of the axial distance  $x$ , the nondimensional velocity function  $f'(\eta)$ , the flow behaviour index  $n$  and consistency index  $K$  of the fluid. The special cases of  $n < 1/2$ ,  $n = 1/2$  and  $n = 1/3$  were also considered separately. It was shown that the volume rate of discharge increases with axial distance.

Gutfinger and Shinnar (4), using a power law viscosity model,

obtained a complete analytical solution, similar to Kapur's, for a two dimensional, liquid into liquid jet. An analysis of the validity of the boundary layer assumptions was also performed. Using flow visualization techniques, they experimentally determined the velocity profiles. In both the Newtonian and non-Newtonian cases studied the agreement between theoretical and experimental velocity profiles was reasonable. The differences could have been due to the method they employed to measure the velocity profiles. During their experiment it was noticed that when the kinematic momentum of the non-Newtonian jet was equal to  $1500 \text{ ml/s}^2$  the jet immediately spread to the sides and no clearly defined jet could be seen. They were not able to explain this phenomena.

Lemieux and Unny (8) obtained a numerical solution for a two dimensional, pseudoplastic, free jet by using a power law model. An empirical relation for the width of the jet was found to be

$$b = (\text{constant}) x^{2/3n} \quad (2.1)$$

It can be seen that the jet boundaries are linear when  $n = 2/3$ , concave for  $n > 2/3$  and convex for  $n < 2/3$ . The authors reasoned that, because the non-dimensional velocity,  $F'(\xi)$ , tends to zero as the non-dimensional radial distance approaches infinity, the non-dimensional stream function,  $F(\xi)$ , should tend to a finite value. Later this was proven to be incorrect by Atkinson (1). In his analytical solution it was shown that  $F'(\xi)$  tends to infinity as  $\xi$  tends to infinity.

Serth (19) obtained a numerical solution for an axisymmetric free laminar jet of a power law fluid with  $n > 1/2$ . Experimental velocity profiles using Separan AP30 having values of  $n = 0.57$  and  $K = 1.25 \text{ dyne sec/cm}^2$  were also presented. A similar effect as that observed by Gutfinger and Shinnar was also noted in this study. A sharp drop in the velocity occurred as the jet came out of the orifice due to the expansion of the jet. Theoretical predictions failed in this region, however, at some distance away from the exit, the theoretical predictions were in good agreement. It was also shown that the axial velocity decay was proportional to  $1/(2n-1)$ .

Nystrom et al. (15) have provided an extensive review on mixing and drag reduction in non-Newtonian jets. It was shown, using the similarity principle, that for a turbulent jet there was no distinction in the gross characteristics between the Newtonian and non-Newtonian cases. Their experiments with POLYOX WSR-301 also supported this conclusion. In view of the fact that they used a fluid which had a flow behaviour index very close to unity ( $n = 0.9$ ) differences between the Newtonian and non-Newtonian jet may not have been appreciable. The use of a probe to measure the velocity profiles may have introduced some errors. Further experiments using fluids having a much lower value of flow behaviour index and employing non-invasive techniques for velocity measurement are needed to confirm their conclusion.

Mitwally (14) obtained numerical solutions for an axisymmetric jet of non-Newtonian power law fluids. Solutions for plane and radial wall jets were also given. The governing non-linear partial differen-

tial equations were reduced to ordinary differential equations by suitable transformations and then solved numerically. One of the main conclusions is that a pseudoplastic fluid with  $0.5 < n < 1$  starting as a laminar jet, will continue to be laminar\* further downstream. This is expected due to the prediction that the jet Reynolds number decreases with axial distance.

## 2.2 Laminar Length Measurements

All of the research work cited below is concerned with experimental determination of the laminar length of Newtonian jets which are either compressible or incompressible.

McKenzie and Wall (12) studied the laminar length of a submerged jet in the Reynolds number range of 5 to 400 for both the compressible and incompressible cases. They used a birefringent liquid for the incompressible jet study and a Helium-Air combination for the compressible jet study. The empirical relationship proposed by them for the laminar length is

$$\frac{L}{d} = \frac{1000}{Re} \quad (2.2)$$

Reynolds (18) observed the flow of a dyed water jet into a tank of water. He noticed five different modes of breakdown of the jet depending on the Reynolds number. He indicated them on a plot of laminar length versus Reynolds number.

McNaughton and Sinclair (13) investigated a water into water jet using a tracer solution. They photographed the tracer solution jet flowing into a water tank. They also studied the variation

of laminar length with jet chamber diameter and length. Their empirical relation is

$$\frac{L}{d} = (9.97 \times 10^7)(Re^{-2.46})(\frac{D}{d})^{-0.48}(\frac{L}{d})^{0.74} \quad (2.3)$$

for  $500 < Re < 2000$ ;  $3 < L/d < 8$  and  $3 < D/d < 24$

Marsters (10) measured the laminar length of a carbon dioxide jet issuing into air using the Shadowgraph technique. Ethylene was also used as a jet gas. He used several combinations of supply tube material, length and diameter and proposed an empirical correlation between the laminar length and Reynolds number for  $1000 < Re < 2400$  as

$$\frac{L}{d} = (10^9)(Re^{-2.3}) \quad (2.4)$$

Beatty and Markland (2) did a similar study and determined that the upstream conditions had no significant effect on the laminar length.

### 2.3 Properties of the Non-Newtonian Fluid

The non-Newtonian fluid selected for the present experiment is a dye solution which can be prepared by mixing Milling Yellow powder with boiling water. This survey is concerned with the birefringent property and with measurement of the viscosity of the Milling Yellow dye solution.

The first investigator to use Milling Yellow as a birefringent fluid was Prados (16). In his dissertation on the analysis of two dimensional laminar flows, he determined the velocity profiles from

the interference patterns after suitable optical calibration of the fluid. This fluid behaved essentially in a Newtonian manner as the maximum experimental shear rate encountered was about  $10 \text{ sec}^{-1}$ .

Hirsch (5) performed experiments in such a shear rate range that the fluid behaved in a non-Newtonian manner. He measured velocity profiles in a diverging duct using the birefringent flow visualization technique. His measured velocity profiles and theoretical velocity profiles agreed very well. He has also given a rigorous procedure for preparing the Milling Yellow solution.

Hui Pih (6) presented a review of the application of birefringent flow visualization technique in various flow situations. He also indicated the usefulness of Milling Yellow for birefringent studies.

Maron et al (9) described an accurate and convenient method of determining the flow curves of non-Newtonian fluids using a "falling head" capillary viscometer. In this method a driving fluid is used to force the non-Newtonian fluid through a capillary tube. The measurement of the height of the driving fluid column as a function of time leads to the determination of the flow curve.

Walawender and Chen (21) used a similar approach to obtain the viscosity of non-Newtonian fluids. The only difference in their method is that instead of using a different driving fluid, the test fluid flows through the capillary tube under its own head. Using non-linear curve fitting techniques, an empirical relationship between the falling head and time was obtained and from this the viscosity was determined.

## CHAPTER III

### FLOW VISUALIZATION AND THE NON-NEWTONIAN FLUID

A brief explanation of the flow visualization technique employed in the present study and a discussion concerning the non-Newtonian behaviour of the Milling Yellow solution is presented in this chapter.

#### 3.1 Flow Visualization

Flow visualization plays an important role in many fluid flow problems. These techniques can provide an image of the entire flow field, unlike other flow measuring instruments, which give only localized information. It is also possible with these techniques to obtain quantitative information about the flow situation without disturbing it.

One of the methods employed in visualizing the flow is called the double refraction or birefringent technique. Birefringence is present in both solids and liquids and is an optical characteristic of the medium which is described as follows. When a birefringent fluid is at rest, it is optically isotropic; that is the refractive index of the fluid is the same in all directions. As soon as it is set into motion, it becomes optically anisotropic. When a linearly polarized light ray is incident upon such a medium, it is divided or refracted into two linearly polarized light components with their planes of polarization perpendicular to each other. One of the rays is called the 'ordinary ray' and the other the 'extraordinary ray'. They travel through the medium at different velocities. When they leave the medium, a relative angular phase shift exists between them. This phase shift is given by

$$\Delta\theta = \frac{2\pi dm}{\lambda} (\omega_e - \omega_o) \quad (3.1)$$

where  $dm$  is the thickness of the medium,  $\lambda$  is the wavelength of the light and  $\omega_e$  and  $\omega_o$  are the medium's extraordinary and ordinary index of refraction respectively. The difference in the refractive indices,  $\omega_e - \omega_o$ , is proportional to the difference of principal strains and hence to the difference of principal stresses. A polariscope is used to observe this phase difference. It provides an image of the stress distribution over the flow field. Depending on whether the light employed to make the stress pattern visible is circularly polarized or linearly polarized the polariscope is called a circular polariscope or a plane polariscope. The following explanation concerning the operation of a polariscope is limited only to a circular polariscope as it is the one used in the present study. Figure 3.1 illustrates the general arrangement of a circular polariscope.

The circular polariscope consists of a light source, polarizer, two quarter-wave plates and analyzer. In the "dark field" arrangement of a circular polariscope the polarization axis of the polarizer and the analyzer are crossed; that is oriented perpendicular to each other. The fast and slow axis of the two quarter-wave plates are also crossed and arranged in such a manner that they are at  $45^\circ$  with respect to the polarizer axis. The light coming from the source first passes through the polarizer. The linearly polarized light from the polarizer then passes through the first quarter-wave plate which splits it into two

orthogonal components. These two rays travel at different velocities and are retarded relative to one another by an amount  $\lambda/4$  when they emerge from the quarter-wave plate. This produces circularly polarized light which enters the test chamber containing the birefringent fluid. Only the components of these two rays along the principal axes of the flow field emerge from the test chamber and have an additional relative phase shift. The second quarter-wave plate resolves these rays into two orthogonal components and introduces a relative retardation of  $\lambda/4$  between the two rays opposite to that occurring in the first quarter-wave plate. The main objective of the second quarter-wave plate is to convert the circularly polarized light of the first quarter-wave plate to linearly polarized light. When the two rays emerge from the second quarter-wave plate they pass through the analyzer. The analyzer passes only the resultant of these two rays along its axis of polarization. A fringe pattern is produced when these two rays interfere along the analyzer axis.

Fringes do not appear in the flow field when it is stationary because of the absence of shear stresses. Once the flow is initiated, the flow field is subjected to the action of shear stresses and hence fringe patterns are visible. When white light is used as the source, the fringe pattern will appear as a series of coloured bands. When the light employed is monochromatic, the fringe pattern will be a series of dark bands. These dark fringes are called isochromates. Each fringe corresponds to a given value of shear stress.

Dark fringes also appear in the case of a plane polariscope employing a monochromatic light source. The fringe pattern may be composed

of both isochromates and isoclinics. Isoclinic fringes appear when the direction of the principal stresses coincides with the direction of polarization. In a circular polariscope only the isochromatic fringes appear and the isoclinics are eliminated.

Flow parameters such as velocity and shear rate can quantitatively be estimated from the interference fringe patterns obtained in an unknown flow situation after calibrating the given liquid under known shear stress conditions. In the present study the only quantitative measurement to be made is the length of the laminar jet which corresponds to the length of the "ordered" isochromatic fringe pattern. In a laminar-turbulent jet the fringe patterns are ordered and stationary in the laminar region whereas in the turbulent region the ordered pattern is broken up. Hence, irregular, non stationary patterns are formed. The distance from the jet exit to the point where the pattern is no longer regular and stationary is defined as the laminar length of the jet.

### 3.2 Non-Newtonian Fluids

Skelland (20) defines non-Newtonian fluids as those fluids for which the flow curve is not linear through the origin at a given temperature and pressure. The viscosity may be dependent on the shear rate or on the duration of the shear rate and the past history of the fluid.

Skelland (20) classifies non-Newtonian fluids into three major groups. They are

- (a) Time-independent fluids
- (b) Time-dependent fluids
- (c) Viscoelastic fluids.

A time-independent fluid has the characteristic that the rate of shear depends only on the local shear stress whereas in a time-dependent fluid shear rate depends on the magnitude and duration of the shear stress as well as on the past history of the shear stress. Viscoelastic fluids exhibit the properties of both fluids and elastic solids. The fluid selected for the present study falls into the time-independent category and hence a brief explanation of the behaviour of such fluids will be given.

Milling Yellow falls into the group of time-independent substances which do not have yield stress. Figure 3.2 illustrates the flow curves of various types of time-independent fluids. There are two common types of fluids in this category. They are called pseudoplastic or dilatant depending on whether their viscosity decreases or increases with shear rate respectively. Milling Yellow is found to exhibit pseudoplastic behaviour. A typical viscosity curve of a Milling Yellow solution is given in Figure 3.3. Three distinct regions may be identified. In the low shear rate region, the fluid is Newtonian and the viscosity,  $\eta_0$ , remains nearly constant. The viscosity varies with shear rate in the intermediate region and again remains nearly constant,  $\eta_\infty$ , in the high shear rate region. In the non-Newtonian region, which has a shear rate range of approximately 50 to 800  $\text{s}^{-1}$ , the following equation is

found to fit the experimental data quite well

$$\tau = K(\dot{\gamma})^n \quad (3.2)$$

This equation is referred to as the "Power law" viscosity model. The values of K and n depend upon the type of fluid and concentration. The value of n is always less than unity for pseudoplastic fluids and greater than unity for dilatant fluids.

## CHAPTER IV

### EXPERIMENTAL DETAILS

#### 4.1 Introduction

This chapter describes the experimental facility that was constructed for the measurement of laminar length and viscosity. It also includes a description of the experimental procedure that was adopted. A discussion concerning the selection of the working fluid is also given.

#### 4.2 Selection of Working Fluid

The working fluid selection was based on the following two criteria:

- (1) It should be birefringent.
- (2) It should exhibit time-independent non-Newtonian behaviour.

Milling Yellow satisfies both of these requirements. There are, of course, many other fluids such as Vanadium-pentoxide and Polyisobutylene which satisfy the above two requirements. Milling Yellow also exhibits the following desirable properties which the other fluids do not.

- (a) High optical sensitivity.
- (b) Moderate viscosity.
- (c) Stability in contact with most of the common construction materials.

(d) Relatively easy to prepare.

Milling Yellow was therefore selected as the working fluid.

A detailed description concerning the preparation of the Milling Yellow solution is given in Appendix (A).

#### 4.3 General Test Facility

Figure 4.1 shows a schematic diagram of the test facility constructed for this investigation.

##### 4.3.1 Fluid Flow Unit

The fluid flow unit consisted of the upstream tank, supply tube, jet chamber and the downstream tank. The fluid flows from the upstream tank to the jet chamber through the supply tube. From the jet chamber it flows through plastic tubing to the downstream tank. A brief description of the details of each of the components in the fluid flow unit is given below.

The upstream tank was made of plexiglass. It was circular in cross section with an inner diameter of 152 mm, thickness of 5 mm and a length of 356 mm. It was fixed onto the main supporting frame and its position was not changed during the experiment.

The supply tube consisted of a capillary tube with a diameter of 1.42 mm. It was made of stainless steel and was 305 mm in length. The capillary tube was housed inside a larger diameter tube in order to maintain straightness. The supply tube was connected to the upstream tank by means of a bellmouth entrance. This ensured smooth entry of fluid from the upstream tank. The other end of the supply tube was fixed so that it was flush with the upper wall of the

jet chamber.

The jet chamber was square in cross section and also made of plexiglass. The inner dimensions of the chamber were 102 x 102 mm. The wall thickness and the length were 9 mm and 254 mm respectively. A bleed port was provided and used to remove any air trapped inside.

The axes of the upstream tank, supply tube and the jet chamber were all on the same line. To ensure this alignment, holes were drilled in the corners of the square flanges that were mounted on the end of the upstream tank and jet chamber. An Aluminium rod was inserted in each set of holes. Only when the upstream tank and jet chamber were in alignment could these rods pass through the holes and be fixed in place.

The downstream tank was similar, in its dimensions, to the upstream tank. It was connected to the jet chamber by means of a 2.90 m. long and 12.70 mm diameter plastic tubing. A valve was located underneath the downstream tank. Unlike the upstream tank, the position of the downstream tank was not fixed. Setting different elevations of this tank was required to cover the desired range of Reynolds number. It was always kept at a lower level than the upstream tank.

#### 4.3.2 Instrumentation

The fluid in the upstream tank flows into the downstream tank when the flow is started. As the upstream and downstream tanks are identical in all dimensions, the drop in the level of liquid in one tank will be equal to the rise in the other. Hence it is sufficient to measure the liquid level in any one of the tanks. In order to determine the viscosity and the flowrate it was necessary to know only the time rate

of change of head and not the actual head. The method described below was used to measure this change in head..

A depth gauge and a simple electric circuit were used to measure the liquid level in the downstream tank. A thin copper rod, with a sharp tip, was fixed to a vernier scale. This unit was called the depth gauge and was mounted on the downstream tank. An electric circuit was formed consisting of a power supply, an indicator light, the copper rod, the downstream tank and the fluid in the tank. In order to measure the liquid level, first the copper rod was positioned so that it touched the surface of the fluid. This was done before the flow was started. Once the flow was initiated the vernier scale was moved up, by a known distance so that the top of the copper rod was at a higher level than the level of the liquid. As the level of liquid in the downstream tank was increasing, after some time the surface of the liquid touched the top of the copper rod. As soon as this contact was made, the circuit was closed and current flowed which made the light go on. In this way the rise of liquid level at various instants of time, was measured. In order to determine the actual difference in the levels of the liquid at any time, it was sufficient to know the difference in the levels before the flow was started and the rise in the liquid level up to that time.

In order to measure the laminar length of the jet, a photographic technique was first attempted. Photographs of the fringe patterns were taken and then projected onto a large screen using a film strip projector. The intensity of the polarized light, which

made the fringes visible, was very low and hence the quality of the pictures was not good. To locate the transition point from these photographs was very difficult. The photographic method provided only a static view of the jet at a particular instant of time and did not give any information on the unsteady nature of the flow. Hence the photographic method was abandoned and a direct measurement technique employed. In this method the transition point could be easily located by identifying the intersection of the unsteady turbulent region and steady laminar region.

A displacement transducer and a digital read-out unit were employed to measure the laminar length. The main body of the transducer was mounted onto the side of the jet chamber. The "slider" of the transducer was fastened to a metal block which moved along a guide-way. Two thin metallic wires were fixed to the guide block. Both wires were horizontal and parallel to each other, however, one was located in front of and one behind the jet chamber. They could be positioned along the length of the jet chamber and were parallel to the front and rear faces. In order to take a reading, the operator's eye was positioned in such a way that both wires were aligned and appeared to be a single wire. In this way the parallax error was eliminated. The digital read-out unit, which was connected to the transducer, gave the displacement of the wires from the exit of the capillary tube.

#### 4.3.3 Polariscope

The polariscope used in the present study is shown in Figure

4.2. It consisted of a light source, a polarizer, two quarter-wave plates and an analyzer. It could be operated either as a plane polariscope or as a circular polariscope. In the present study it was operated as a dark field circular polariscope.

The light source consisted of a bank of six fluorescent tubes mounted behind a diffusing screen. This provided a uniform illumination over the entire flow field.

The polarizer and the first quarter-wave plate were mounted as a single unit. Similarly the second quarter-wave plate and the analyzer were mounted as a single unit. This distance between these two units was approximately 480 mm. The polarizer, the two quarter-wave plates and the analyzer were 203 mm in diameter.

#### 4.3.4 Rheometer

The rheological behaviour of the Milling Yellow solution was determined with the aid of a rotary viscometer. Figure 4.3 is a photo of the Contraves Rheomat 30 viscometer that was used in the present study. It consisted of a bob rotating concentrically inside a cup. The cup and bob combination is referred to as the measuring system. Depending upon the viscosity of the fluid and the shear rate desired, the proper measuring system was selected. Measuring system A had a shear rate range of  $8.99 \times 10^{-2}$  to  $662 \text{ sec}^{-1}$  and was used in the present study. The shear rate was varied by changing the rotational speed of the bob.

#### 4.3.5 Main Supporting Frame

The main supporting frame was made of mild steel 'L' sections.

The frame was rectangular in cross section (406 x 584 mm) and stood 1.5 m high. Cross bars along the length of the frame provided means to position the upstream tank at different heights. This frame was bolted rigidly to a laboratory table. The table was of solid construction and also supported the polariscope.

#### 4.4 Experimental Procedure

In this section the procedures associated with the experimental determination of the laminar length and the viscosity are described in detail. The experimental procedure described below, excluding 4.4.2, was adopted for fluids of different concentrations.

##### 4.4.1 Preparation of the Working Fluid

The first step in the experiment was to prepare a birefringent solution of Milling Yellow. Such a fluid was prepared using the detailed procedure given in Appendix (A).

##### 4.4.2 Determination of the Diameter of the Capillary Tube

An accurate value of the diameter of the capillary tube was required to determine the viscosity of the fluid. Extreme care was taken to determine the diameter of the tube. Mercury was allowed to flow through the tube which eliminated any trapped air. The flow was then stopped and the excess Mercury at the inlet removed. The Mercury that remained inside the tube was then collected and weighed. The diameter of the tube was determined by using the equation

$$d = \left( \frac{4m}{\pi \rho_{Hg}} \right)^{1/2} \quad 4.1$$

where  $d$  and  $l$  are the diameter and length of the tube respectively,  $m$  is the mass of the Mercury collected and  $\rho_{\text{Hg}}$  is the density of the Mercury at the test temperature.

#### 4.4.3 Initial Setup Procedure

The fluid flow unit was mounted on the main supporting frame in such a way that the jet chamber was located midway between the analyzer and polarizer. The entire unit was mounted such that the capillary tube was vertical. After aligning the two faces of the jet chamber parallel to the quarter-wave plates, the unit was clamped rigidly to the frame. The downstream tank, which included the depth gauge assembly, was positioned at the desired elevation. The fluid was then introduced into the system. Care was taken to remove any air that was trapped inside the jet chamber.

The polarizer, two quarter-wave plates and analyzer were arranged to operate as a circular polariscope.

The digital read-out was initialized by positioning the two wires attached to the slider of the displacement transducer at the jet exit. The readout was then set to zero and the temperature of the fluid also recorded.

#### 4.4.4 Laminar Length Measurements

The flow was initiated and a stopwatch started at the same instant. Even though white light was used for visualization only dark and light (yellow) fringes were visible in the flow field and the transition point could be clearly identified. Figure 4.4 is a photograph of the fringe pattern obtained for a laminar-turbulent jet.

---

The wire assembly connected to the transducer was then moved to coincide with this laminar to turbulent transition point. The reading on the digital read-out was recorded when the two wires appeared as a single wire when viewed through the analyzer. For each laminar length reading the corresponding time on the stopwatch was also noted.

#### 4.4.5 Viscosity Measurements

It was necessary to know the head versus time relationship in order to determine the viscosity of the fluid using the experimental facility. The depth gauge and stopwatch readings were recorded simultaneously at approximately equal intervals of head for this purpose. The temperature of the fluid was also noted at regular intervals of time.

The viscosity of the fluid was also determined by using the Rheomat described in 4.3.4. The viscosity of a sample of the fluid at various shear rates was determined.

In order to cover the desired range of laminar length and viscosity it was necessary to perform the experiment with different elevation settings of the downstream tank.

The initial difference in the levels of liquid was relatively small for some downstream tank settings. The experimental time was very long using such settings. To minimize this time it was decided to reduce the diameter of the upstream and downstream tanks. This was accomplished by installing two smaller diameter tanks inside the original, larger diameter tanks. The new tanks were 356 mm in length and 50.8 mm in diameter. This reduced the experimental time considerably.

## CHAPTER V

RESULTS AND DISCUSSION

The laminar length and viscosity data obtained in the present experimental study are presented in Tables 4. through 24. The results are discussed in detail in the following section.

5.1 Laminar Length of the Jet

The measured laminar length of the jet is non-dimensionalized by dividing it by the diameter of the supply tube. This is referred to as the laminar length,  $N_L$ . Tables 17 to 24 represent the laminar length data. For any particular head difference (and hence maximum shear rate) the Reynolds number represented in the table is calculated using the diameter of the tube, the average velocity in the tube and viscosity of the fluid.

Figure 5.1 illustrates the variation of laminar length,  $N_L$ , with Reynolds number,  $Re$ , for two different concentrations of the fluid. From the figure it can be seen that the laminar length increases in the Reynolds number range of 50 to 200. The variation of laminar length is different for the two concentrations. Very low intensity of the fringes in this range made it difficult to locate the exact point after which the jet completely diffused into the surrounding fluid. This is the reason for the scattering of the data for both concentrations. The laminar length data for both concentrations coalesce for  $200 < Re < 350$ . For Reynolds numbers greater than 350 and up to 600, the laminar length of the jet was more than the diameter of the analyzer. Hence laminar length measurements could not be taken in this range. In the Reynolds number range of 600 to 700 of a laminar-turbulent jet, the data indicate

a sharp drop in the laminar length. In this range of Reynolds number, the laminar length was unsteady and fluctuated considerably and hence only the mean value of the fluctuations are shown in Figure 5.1. For Reynolds numbers greater than 700, the laminar length decreases less sharply with the Reynolds number.

From Figure 5.1 it can be seen that, for a laminar-turbulent jet ( $600 < Re < 1100$ ) there is little difference in the variation of the laminar length with Reynolds number for the two concentrations. The lack of dependence of laminar length on the concentration (and hence on the rheological properties of the fluid) may be due to the fact that the turbulent stresses in the jet dominate over the viscous stresses. In the case of a fully laminar jet and in the Reynolds number range of 50 to 200, the variations of laminar length with Reynolds number are appreciably different for the two concentrations. This may be due to the fact that turbulent stresses are absent and the laminar length depends on parameters in addition to Reynolds number as defined here.

The variation laminar length with Reynolds number is correlated using a curve fitting technique for a Reynolds number range of 650 to 1000. The empirical relation obtained is

$$N_L = A Re^B \quad (5.1)$$

where  $A = 9.5 \times 10^7$   
 $B = -2.23$  and  $\epsilon = 0.1$

In Figure 5.2 the results of the present study are compared with some of the similar Newtonian studies. In the case of a laminar-turbulent jet ( $600 < Re < 1100$ ) the present results compare well with

the results given by McNaughton and Sinclair [13] for liquid jets.

The lack of agreement between the present results and those of McKenzie and Wall [12] could be attributed to the fact that their results were taken with jets which were neither axisymmetric nor free. The agreement of the present study with the results of Beatty and Markland [2] and with those of Marsters [10] is more reasonable than the agreement between the present study and Reference 12. The present data and Marster's [10] results show a good agreement in the slope of the plot of  $N_L$  vs  $Re$ . However the difference between the  $N_L$  values of the two studies cannot be explained by the uncertainty of the present data. We should also note that the results of Beatty and Markland [2] and Marters [10] were taken using gaseous jets. It can also be seen that in the case of fully laminar jets ( $50 < Re < 350$ ) the present results do not compare well with those of Beatty and Markland [2]. As mentioned earlier, the reason could be that the non-Newtonian nature of the fluid influences the laminar length of a fully laminar jet and unlike the Newtonian jet, Reynolds number is not sufficient to collapse the data.

Mitwally [14] speculated, as mentioned in Chapter II, that when the flow behaviour index,  $n$ , of a pseudoplastic fluid is between 0.5 and 1 and if a submerged jet of this fluid begins as a laminar jet, the jet will never become turbulent. In the present experiment the fluid used was pseudoplastic in nature and the value of  $n$  was between 0.5 and 1. For  $600 < Re < 1100$  it was observed that the jet indeed did become turbulent even though it was laminar at the exit of the tube. This shows that the instability of a submerged jet cannot be based upon

the variation of the local Reynolds number (in which  $n$  is the important parameter) as defined by Mitwally.

## 5.2 Viscosity Measurements

The experimental data obtained from the rotary viscometer (Rheomat) and from the present experimental facility are presented in Tables 2 through 16. The procedure that was used to determine the viscosity of the fluid from the head versus time data is given in Appendix (B).

The variation of viscosity with shear rate obtained from the rotary viscometer and from the present test facility using it as a capillary viscometer are given in Figures 5.3 and 5.4 for the two fluid concentrations used. The capillary viscometer is capable of yielding a continuous curve of the viscosity variation over a wide range of shear rates ( $10 < \dot{\gamma} < 9000$ ). The agreement between the rotary viscometer results and the capillary viscometer results is reasonably good in trend only. At low shear rates ( $0 < \dot{\gamma} < 20$ ) and at high shear rates ( $500 < \dot{\gamma} < 660$ ) the viscosity values given by the rotary viscometer disagree with the capillary viscometer values. The reason for the disagreement could be that the relatively low viscosity of the fluid makes it unsuitable for testing with the rotary viscometer.

Even though the tests were conducted during a period of the day when the room temperature fluctuation was minimum, the variation of temperature between and during runs could not be avoided. This may be one of the reasons for the slight discontinuities in the viscosity curve. It is speculated that a better curve fitting technique would give a more continuous variation.

## CHAPTER VI

CONCLUSIONS AND RECOMMENDATIONS6.1 Conclusions

The variation of the laminar length with Reynolds number is experimentally obtained for a submerged, axisymmetric jet of a non-Newtonian fluid. From this information the following conclusions are made.

(a) The laminar length of a laminar-turbulent jet ( $600 < Re < 1100$ ) is independent of the concentration and hence the non-Newtonian nature of the fluid.

(b) The non-Newtonian nature has a substantial effect on the laminar length of a fully laminar jet ( $50 < Re < 200$ ).

(c) The present results compare well with the results of McNaughton and Sinclair [13] for laminar-turbulent liquid jets.

The variation of the viscosity of the non-Newtonian fluid with shear rate is obtained using the present test facility. The agreement between the rotary viscometer results and capillary viscometer results is reasonably good in trend only.

6.2 Recommendations

(1) Variation of the temperature of the fluid during tests should be minimized by using a temperature controlled bath.

(2) Further experiments should be performed to verify the conclusions of the present study, with few changes in the present experimental facility and with fluids having values of  $n$  less than 0.5.

(3) Further experiments could be carried out using different diameters of the supply tube and different sizes of test chamber to observe whether the laminar length is affected by these changes.

## APPENDIX A

Preparation of Milling Yellow Solution

Milling Yellow is available in powdered form. The dye powder is bright yellow in colour and has a low density. It can be obtained from Keystone Aniline and Chemicals Co., Chicago, Illinois, U.S.A. The dye used in the present study was Keyacid Milling Yellow 3NGS code 801-044-51-5, Lot B2109. The procedure for preparing the solution is given below.

(a) Distilled water was brought to boiling state as the dye powder does not dissolve in water at room temperature.

(b) Dye powder in the amount that yielded a solution of 1% by weight was then added to the boiling water in small batches. This is the maximum concentration that can be prepared initially. To obtain solutions of higher concentration, the 1% solution must be heated to evaporate the excess water.

(c) Each time the dye powder was added the solution was stirred continuously to dissolve it completely.

(d) The solution was then allowed to cool down to room temperature.

(e) The pH value of the solution has to be approximately 7 in order to obtain a fluid which has good birefringent characteristics. For this purpose, a small amount of phosphoric acid (40% concentration) was added to the solution. Instead of measuring the pH value, in the present work, the solution was placed between the polarizer and analyzer and stirred continuously in order to produce motion. Acid was added until satisfactory clarity and birefringent characteristic (fringes)

were achieved.

(f) The solution was heated to increase the concentration to values above 1%, when required.

(g) The solution was then stored in plastic container.

In the present study, solutions having concentrations of 1.204% and 1.135% were used.

Major factors which influence the birefringent characteristics of the fluid are its concentration, acidity and age. Prolonged storage of a solution improves its birefringence. Solutions having a concentration of 1% by weight and greater are quite birefringent. A higher concentration, however, yields a more viscous solution. Solutions having concentration in the range of 1.2% to 1.6% have ideal properties.

## APPENDIX B

### Viscosity Determination using Non-Linear Parameter Estimation Technique and "Falling Head" Capillary Viscometer

One of the most common instruments used to determine the rheological properties of a Non-Newtonian fluid is a capillary viscometer. The experimental set up used for measuring the laminar length in the present study also serves as a capillary viscometer. In a capillary viscometer the flow rate of the fluid and the corresponding frictional pressure drop are measured. This is accomplished by measuring the drop in head and the corresponding interval of time. From the relationship between the head and time, the viscosity of the fluid at various shear rates can be deduced. In order to establish the relationship between the head and time, a curve fitting technique based on the least square method is employed.

Before discussing the above mentioned parameter estimation technique, it is necessary to develop the relationship used to determine the viscosity of the fluid. This formulation is already presented in references [8] and [20]. However, for the sake of completeness it is given here.

Fluid from the upstream tank flows into the downstream tank due to the head difference. Let  $h_i$  be the difference in levels of the fluid in the upstream and downstream tank at time  $t$ . If  $\Delta h$  is the drop in the liquid level in one of the tanks during the time interval  $\Delta t$ , the head difference at time  $t + \Delta t$  is given by  $h = h_i - 2(\Delta h)$ .

The flow rate can be written as

$$Q = A_T \frac{\Delta h}{\Delta t} \quad \dots (B.1)$$

where  $A_T$  is the area of the upstream tank. Neglecting minor losses, we can write the pressure drop as

$$\Delta p = \rho g h \quad \dots (B.2)$$

For steady, fully developed flow of a Non-Newtonian, time independent fluid through a vertical capillary tube (Ref. [19]) the wall shear stress is

$$\tau_w = \frac{R \Delta p}{2\ell} = \frac{R \rho g h}{2\ell} \quad \dots (B.3)$$

and the shear rate,

$$\dot{\gamma} = f(\tau) \quad \dots (B.4)$$

It can be shown that

$$\frac{Q}{\pi R^3} = \frac{1}{3} \frac{1}{\tau_w} \int_0^{\tau_w} \tau^2 f(\tau) d\tau \quad \dots (B.5)$$

and the apparent fluidity is

$$\phi_e = \frac{1}{\eta} = \frac{8LQ}{\pi R^4} \frac{1}{\Delta p} \quad \dots (B.6)$$

Substituting equations (B.1) and (B.2) into (B.6) we obtain

$$\ln h = \left( -\frac{2\pi R^4 \rho g}{8\ell A_T} \phi_e \right) t + c \quad \dots (B.7)$$

Using (B.3) and substituting for  $\Delta p$  in (B.6) yields

$$\phi_e = \frac{4Q}{\pi R^3 \tau_\omega} = \frac{4}{\tau_\omega} \int_0^{\tau_\omega} \tau^2 f(\tau) d\tau \quad \dots(B.8)$$

When the above equation is differentiated with respect to  $\tau_\omega$  using Leibnitz's rule we get

$$\frac{d\phi_e}{d\tau_\omega} = -4 \left[ \frac{\phi_e}{\tau_\omega} - \frac{f(\tau_\omega)}{2} \right] \quad \dots(B.9)$$

Rearranging this we obtain

$$\frac{\gamma_\omega}{\tau_\omega} = -\phi_e \left[ 1 + \frac{1}{4} \frac{d \ln \phi_e}{d \ln \tau_\omega} \right] \quad \dots(B.10)$$

Defining  $S = \frac{2\pi R^4 g}{8\lambda A_T}$  and  $m = -S\phi_e$  and by making use of equation (B.3) we can write equation (B.10) as

$$\frac{\gamma_\omega}{\tau_\omega} = -\frac{m}{S\rho} \left[ 1 + \frac{1}{4m^2} \frac{dm}{dt} \right] \quad \dots(B.11)$$

From equation (B.7) we see that

$$m = \frac{d(\ln h)}{dt} \quad \dots(B.12)$$

In order to find out the viscosity of the fluid at a particular shear rate, we need to know the values of  $m$  and  $\frac{dm}{dt}$  at that shear rate.

This is evident from equation (B.11). In other words, once the relationship between  $h$  and  $t$  is known the viscosity determination is simple. A curve fitting technique was employed to formulate this relationship. Two methods, one in the high shear rate region and the other one in the intermediate and low shear rate regions, were used.

A relationship of the form

$$h = A \exp (Bt^2 + Ct) \quad \dots(B.13)$$

was used in the high shear rate region ( $\dot{\gamma} \geq 1000$ ). The parameters  $A$ ,  $B$  and  $C$  were obtained using the least-square principle. Those values of  $A$ ,  $B$  and  $C$  which gave the minimum sum of the error squared were taken to be the best estimates. This method worked very well in the high shear rate region. In low shear rate region this relationship was not a good approximation to the data.

In the low shear rate region a relationship of the form

$$h = \exp (A_0 + A_1 t + A_2 t^2 + \dots + A_n t^n) \text{ where } n \leq 10 \quad \dots(B.14)$$

was used to fit the head-time data. This  $n$ th degree polynomial fitting of the  $\ln h - t$  data gave better results than the previous second degree polynomial fitting.

Curve fitting of the second order polynomial was carried out using a program written in BASIC and run on an APPLE II PLUS computer. The  $n$ th degree polynomial fitting was carried out using a curve fitting package available on the department's IM 70 Minicomputer. A copy of the

BASIC program is given in Appendix C.

Once the parameters were estimated the values of  $m$  and  $\frac{dm}{dt}$  were obtained as

$$m = \frac{d}{dt} (\ln h) = 2Bt + c \quad \dots (B.15)$$

and

$$\frac{dm}{dt} = 2B \quad \dots (B.16)$$

for the second degree polynomial. For the  $n$ th degree polynomial by using equation (B.13)

$$m = A_1 + 2A_2t + 3A_3t^2 + \dots + n A_n t^{n-1} \quad \dots (B.17)$$

and

$$\frac{dm}{dt} = 2A_2 + 6A_3t + 12A_4t^2 + \dots + n(n-1) A_n t^{n-2} \quad \dots (B.18)$$

were found. In order to obtain viscosity, the values of  $m$ ,  $\frac{dm}{dt}$ ,  $S$  and  $p$  were substituted into equation (B.11) which was rearranged as follows:

$$\eta = \frac{1}{\left(\frac{\gamma_\omega}{\tau_\omega}\right)} = \frac{-Sp}{m\left[1 + \frac{1}{4m^2} \frac{dm}{dt}\right]} \quad \dots (B.19)$$

The shear stress was calculated using equation (B.3) and the shear rate was found using

$$\gamma_\omega = \frac{\tau_\omega}{\eta} \quad \dots (B.20)$$

The head-time data that was taken during the present study are given in Tables 4 through 16. The values of viscosity, shear rate and shear stress are also included.

## APPENDIX D

UNCERTAINTY ANALYSIS

The data used in the following analysis are taken for Fluid B.

In this analysis laminar lengths for four different Reynolds number are considered.

$$N_L = 29, \text{ Re} = 815 \quad (\text{Table 21})$$

$$(L = 41.4 \text{ mm})$$

$$N_L = 44.4 \text{ to } 96, \text{ Re} = 648 \quad (\text{Table 21})$$

$$(L = 63 \text{ to } 136 \text{ mm})$$

$$N_L = 120, \text{ Re} = 301 \quad (\text{Table 22})$$

$$(L = 170 \text{ mm})$$

$$N_L = 37.6, \text{ Re} = 148 \quad (\text{Table 24})$$

$$(L = 53.4 \text{ mm})$$

For the uncertainty analysis of viscosity and other related quantities the following data are used.

$$\left. \begin{array}{l} h = 1.9040 \text{ m} \\ t = 0.490.20 \text{ sec} \\ \Delta h = 0.063 \text{ m} \end{array} \right\} \quad (\text{Table 11})$$

The uncertainty in the following quantities are estimated;  $d$ ,  $N_L$ ,  $h$ ,  $\frac{dh}{dt}$ ,  $m$ ,  $\frac{dm}{dt}$ ,  $A_T$ ,  $S$ ,  $\rho$ ,  $\eta$ ,  $\tau_\omega$ ,  $\dot{\gamma}_\omega$ ,  $Q$ ,  $V$  and  $\text{Re}$ .

## (1) Capillary Diameter. (d)

$$d = \left( \frac{4m}{\pi \rho_{\text{Hg}} \ell} \right)^{1/2}$$

where  $m = (4.62 \pm 0.01) \times 10^{-3} \text{ kg}$

$$\ell = (225 \pm 5) \times 10^{-3} \text{ m}$$

$$\rho_{\text{Hg}} = (13.5 \pm 0.2) \times 10^3 \text{ kg/m}^3$$

also

$$\begin{aligned} W_d &= \left[ \left( \frac{\partial d}{\partial m} W_m \right)^2 + \left( \frac{\partial d}{\partial \ell} W_\ell \right)^2 + \left( \frac{\partial d}{\partial \rho_{\text{Hg}}} W_{\rho_{\text{Hg}}} \right)^2 \right]^{1/2} \\ &= \left[ \left( \frac{W_m}{2m} \right)^2 + \left( -\frac{W_\ell}{2\ell} \right)^2 + \left( -\frac{W_{\rho_{\text{Hg}}}}{2\rho_{\text{Hg}}} \right)^2 \right]^{1/2} \times d \end{aligned}$$

which gives  $d = (1.42 \pm 0.02) \times 10^{-3} \text{ m} \quad (\pm 1.4\%)$

(2) Non dimensional Laminar Length. ( $N_L$ )

The uncertainty introduced in the measurement of laminar length,  $L$ , is due to the following:

- The diameter of the wire which is used to locate the transition point.
- The difficulty in locating the transition point by visual observation.

The laminar length,  $L$ , and the corresponding uncertainty,  $W_L$ , for different Reynolds number ranges are estimated as follows:

$$L = (41.4 \pm 2.5) \times 10^{-3} \text{ m } (\pm 6\%) \text{ for } 700 < \text{Re} < 1100$$

$$L = (99 \pm 36) \times 10^{-3} \text{ m } (\pm 35\%) \text{ for } 600 < \text{Re} < 700$$

$$L = (170 \pm 20) \times 10^{-3} \text{ m } (\pm 12\%) \text{ for } 200 < \text{Re} < 350$$

$$L = (53.4 \pm 5.5) \times 10^{-3} \text{ m } (\pm 10\%) \text{ for } 50 < \text{Re} < 200$$

The non dimensional laminar length is given as

$$N_L = \left(\frac{L}{d}\right)$$

where  $d = (1.42 \pm 0.02) \times 10^{-3} \text{ m}$

and the values of  $L$  are as given above.

Also

$$w_{N_L} = \left[ \left( \frac{\partial N_L}{\partial L} w_L \right)^2 + \left( \frac{\partial N_L}{\partial d} w_d \right)^2 \right]^{1/2} = \left[ \left( \frac{w_L}{L} \right)^2 + \left( -\frac{w_d}{d} \right)^2 \right]^{1/2} \times N_L$$

which gives

$N_L = 29 \pm 3$	$(\pm 10\%)$	for $700 < \text{Re} < 1100$
$= 70 \pm 25$	$(\pm 37\%)$	for $600 < \text{Re} < 700$
$= 120 \pm 14$	$(\pm 12\%)$	for $200 < \text{Re} < 350$
$= 37.6 \pm 3.9$	$(\pm 10\%)$	for $50 < \text{Re} < 200$

### (3) Head (h)

The head is calculated using the following equation

$$h = h_i - 2\Delta h$$

where

$$h_i = (2031 \pm 20) \times 10^{-3} \text{ m}$$

$$\Delta h = (63 \pm 2) \times 10^{-3} \text{ m}$$

also

$$\begin{aligned} W_h &= \left[ \left( \frac{\partial h}{\partial h_i} W_{h_i} \right)^2 + \left( \frac{\partial h}{\partial \Delta h} W_{\Delta h} \right)^2 \right]^{1/2} \\ &= \left[ (W_{h_i})^2 + (-2W_{\Delta h})^2 \right]^{1/2} \end{aligned}$$

which gives  $h = (1905 \pm 20) \times 10^{-3} \text{ m} (\pm 1.1\%)$

(4) Slope of  $h$  versus  $t$  ( $dh/dt$ ):

The  $h$  versus  $t$  data are curve fitted using the relation

$$h = A \exp(Bt^2 + Ct)$$

$$\frac{dh}{dt} = A \exp(Bt^2 + Ct) \cdot (2Bt + C)$$

$$= h(2Bt + C)$$

where

$$h = (1904 \pm 20) \times 10^{-3} \text{ m}$$

$$B = 8.76971 \times 10^{-10} \pm 0$$

$$C = -1.30860 \times 10^{-4} \pm 0$$

$$t = (490.2 \pm 0.5) \text{ sec}$$

also

$$W_{dh/dt} = \left[ \left( \frac{\partial (dh/dt)}{\partial h} W_h \right)^2 + \left( \frac{\partial (dh/dt)}{\partial t} W_t \right)^2 \right]^{1/2}$$

which gives

$$\frac{dh}{dt} = (-0.248 \pm 0.003) \times 10^{-3} \frac{\text{m}}{\text{s}} (\pm 1.2\%)$$

(5) Slope of  $(dh/dt)$  versus  $t$ .  $(d^2h/dt^2)$ :

We have  $\frac{dh}{dt} = h(2Bt + C)$

$$\frac{d^2h}{dt^2} = (2Bt + C) \frac{dh}{dt} + 2Bh$$

where

$$B = 8.76971 \times 10^{-10} \pm 0$$

$$C = -1.30860 \times 10^{-4} \pm 0$$

$$t = (490.2 \pm 0.5) \text{ sec}$$

$$h = (1904 \pm 20) \times 10^{-3} \text{ m}$$

$$\frac{dh}{dt} = (-0.248 \pm 0.003) \times 10^{-3} \text{ m/sec}$$

also

$$W_{d^2h/dt^2} = \left\{ \left[ W_h \frac{\partial}{\partial h} \left( \frac{d^2h}{dt^2} \right) \right]^2 + \left[ W_{dh/dt} \frac{\partial}{\partial \frac{dh}{dt}} \left( \frac{d^2h}{dt^2} \right) \right]^2 + \left[ W_t \frac{\partial}{\partial t} \left( \frac{d^2h}{dt^2} \right) \right]^2 \right\}$$

$$= \left\{ [2B W_h]^2 + [(2Bt + C) W_{dh/dt}]^2 + [2B \frac{dh}{dt} W_t]^2 \right\}^{1/2}$$

which gives

$$\frac{d^2h}{dt^2} = (355 \pm 4) \times 10^{-10} \frac{\text{m}}{\text{sec}^2} (\pm 1.1\%)$$

(6) Slope of  $\ln h$  versus  $t$  (n)

$$m = \frac{d}{dt} (\ln h)$$

$$= \frac{1}{h} \frac{dh}{dt}$$

where  $h = (1904 \pm 20) \times 10^{-3} \text{ m}$

$$\frac{dh}{dt} = (-0.248 \pm 0.003) \times 10^{-3} \text{ m/sec}$$

also

$$W_m = \left[ \left( \frac{\partial m}{\partial h} W_h \right)^2 + \left( \frac{\partial m}{\partial dh/dt} W_{dh/dt} \right)^2 \right]^{1/2}$$

$$= \left[ \left( -\frac{W_h}{h} \right)^2 + \left( \frac{W_{dh/dt}}{dh/dt} \right)^2 \right]^{1/2} \times m$$

which gives

$$m = (-130 \pm 2) \times 10^{-6} \text{ ln of head in metres/sec } (\pm 1.5\%)$$

(7) Slope of  $m$  versus  $t$  ( $dm/dt$ )

$$\frac{dm}{dt} = \frac{d}{dt} \left[ \frac{1}{h} \frac{dh}{dt} \right]$$

$$= \frac{1}{h} \left[ \frac{d^2 h}{dt^2} - \frac{1}{h} \left( \frac{dh}{dt} \right)^2 \right]$$

where  $h = (1904 \pm 20) \times 10^{-3} \text{ m}$

$$\frac{dh}{dt} = (-0.248 \pm 0.003) \times 10^{-3} \text{ m/sec}$$

$$\frac{d^2 h}{dt^2} = (355 \pm 4) \times 10^{-10} \text{ m/sec}^2$$

also

$$\frac{W_{dm}}{dt} = \left\{ \left[ W_h \frac{\partial}{\partial h} (dm/dt) \right]^2 + \left[ W_{dh/dt} \frac{\partial}{\partial dh/dt} (dm/dt) \right]^2 + \left[ W_{d^2 h/dt^2} \frac{\partial}{\partial d^2 h/dt^2} (dm/dt) \right]^2 \right\}^{1/2}$$

which gives

$$\frac{dm}{dt} = (7 \pm 5) \times 10^{-10} \text{ ln of head in metres/sec}^2 (\pm 29\%)$$

(8) Area of Tank ( $A_T$ )

$$A_T = \frac{\pi D^2}{4}$$

where

$$D = (152 \pm 3) \times 10^{-3} \text{ m}$$

also

$$W_{A_T} = 2A_T \frac{W_D}{D}$$

which gives

$$A_T = (18.2 \pm 0.7) \times 10^{-3} \text{ m}^2 (\pm 3.9\%)$$

(9) Parameter S

$$S = \frac{2\pi R^4 g}{8\ell A_T} = \frac{\pi d^4 g}{64\ell A_T}$$

where

$$d = (1.42 \pm 0.02) \times 10^{-3} \text{ m}$$

$$\ell = (304 \pm 2) \times 10^{-3} \text{ m}$$

$$A_T = (18.2 \pm 0.7) \times 10^{-3} \text{ m}^2$$

also

$$\begin{aligned} W_S &= \left[ \left( \frac{\partial S}{\partial d} W_d \right)^2 + \left( \frac{\partial S}{\partial A_T} W_{A_T} \right)^2 + \left( \frac{\partial S}{\partial \ell} W_\ell \right)^2 \right]^{1/2} \\ &= S \left[ \left( \frac{4W_d}{d} \right)^2 + \left( -\frac{W_{A_T}}{A_T} \right)^2 + \left( -\frac{W_\ell}{\ell} \right)^2 \right]^{1/2} \end{aligned}$$

which gives

$$S = (3.6 \pm 0.2) \times 10^{-10} \frac{\text{m}^2}{\text{sec}^2} (\pm 5.6\%)$$

(10) Density of Milling Yellow ( $\rho$ )

$$\rho = \frac{m}{V}$$

where

$$m = (29.95 \pm 0.01) \times 10^{-3} \text{ kg}$$

$$V = (30 \pm 0.5) \times 10^{-6} \text{ m}^3$$

also.

$$W_p = \left[ \left( \frac{\partial \rho}{\partial m} W_m \right)^2 + \left( \frac{\partial \rho}{\partial V} W_V \right)^2 \right]^{1/2}$$

$$= \rho \times \left[ \left( \frac{W_m}{m} \right)^2 + \left( -\frac{W_V}{V} \right)^2 \right]^{1/2}$$

which gives

$$\rho = (998 \pm 16) \frac{\text{kg}}{\text{m}^3} (\pm 1.6\%)$$

(11) Apparent Viscosity ( $\eta$ )

$$\eta = \frac{S\rho}{m} \left[ 1 + \frac{1}{4m^2} \left( \frac{dm}{dt} \right)^2 \right]^{-1}$$

where

$$S = (3.6 \pm 0.2) \times 10^{-10} \text{ m}^2/\text{sec}^2$$

$$\rho = (998 \pm 16) \text{ kg/m}^3$$

$$m = (-130 \pm 2) \times 10^{-6} \frac{\text{ln of head in metres}}{\text{sec}}$$

$$\frac{dm}{dt} = (17 \pm 5) \times 10^{-10} \frac{\text{ln of head in metres}}{\text{sec}^2}$$

also

$$W_\eta = \left[ \left( \frac{\partial \eta}{\partial S} W_S \right)^2 + \left( \frac{\partial \eta}{\partial \rho} W_\rho \right)^2 + \left( \frac{\partial \eta}{\partial m} W_m \right)^2 \right. \\ \left. + \left( \frac{\partial \eta}{\partial \frac{dm}{dt}} W_{\frac{dm}{dt}} \right)^2 \right]^{1/2}$$

which gives

$$\eta = (2.67 \pm 0.17) \times 10^{-3} \text{ Pa sec } (\pm 6.4\%)$$

(12) Wall Shear Stress ( $\tau_w$ )

$$\tau_w = \frac{R\rho gh}{2\ell} = \frac{\rho gh d}{4\ell}$$

where  $d = (1.42 \pm 0.02) \times 10^{-3} \text{ m}$

$$\rho = (998 \pm 16) \text{ kg/m}^3$$

$$h = (1904 \pm 20) \times 10^{-3} \text{ m}$$

$$\ell = (304 \pm 2) \times 10^{-3} \text{ m}$$

also

$$\begin{aligned} W_{\tau_{\omega}} &= \left[ \left( \frac{\partial \tau_{\omega}}{\partial d} W_d \right)^2 + \left( \frac{\partial \tau_{\omega}}{\partial \ell} W_{\ell} \right)^2 \right. \\ &\quad \left. + \left( \frac{\partial \tau_{\omega}}{\partial h} W_h \right)^2 + \left( \frac{\partial \tau_{\omega}}{\partial \rho} W_{\rho} \right)^2 \right]^{1/2} \\ &= \tau_{\omega} \times \left[ \left( \frac{W_d}{d} \right)^2 + \left( -\frac{W_{\ell}}{\ell} \right)^2 + \left( \frac{W_h}{h} \right)^2 \right. \\ &\quad \left. + \left( \frac{W_{\rho}}{\rho} \right)^2 \right]^{1/2} \end{aligned}$$

which gives  $\tau_{\omega} = (21.77 \pm 0.54) \text{ Pa } (\pm 2.5\%)$

### (13) Wall Shear Rate ( $\dot{\gamma}_{\omega}$ )

$$\dot{\gamma}_{\omega} = \tau_{\omega} / \eta$$

where  $\tau_{\omega} = (21.77 \pm 0.54) \text{ Pa}$

$$\eta = (2.67 \pm 0.17) \times 10^{-3} \text{ Pa s}$$

also

$$\begin{aligned} W_{\dot{\gamma}_{\omega}} &= \left[ \left( \frac{\partial \dot{\gamma}_{\omega}}{\partial \eta} W_{\eta} \right)^2 + \left( \frac{\partial \dot{\gamma}_{\omega}}{\partial \tau_{\omega}} W_{\tau_{\omega}} \right)^2 \right]^{1/2} \\ &= \dot{\gamma}_{\omega} \times \left[ \left( -\frac{W_{\eta}}{\eta} \right)^2 + \left( \frac{W_{\tau_{\omega}}}{\tau_{\omega}} \right)^2 \right]^{1/2} \end{aligned}$$

which gives

$$\dot{\gamma}_{\omega} = (8.154 \pm 0.555) \times 10^3 \text{ sec}^{-1} (\pm 6.8\%)$$

## (14) Volumetric Flow Rate (Q)

$$Q = - \frac{A_T}{2} \frac{dh}{dt}$$

where  $A_T = (18.2 \pm 0.7) \times 10^{-3} \text{ m}^2$

$$\frac{dh}{dt} = (-0.248 \pm 0.003) \times 10^{-3} \text{ m/sec}$$

also

$$\begin{aligned} W_Q &= \left[ \left( \frac{\partial Q}{\partial A_T} W_{A_T} \right)^2 + \left( \frac{\partial Q}{\partial \frac{dh}{dt}} W_{\frac{dh}{dt}} \right)^2 \right]^{1/2} \\ &= Q \times \left[ \left( -\frac{W_{A_T}}{A_T} \right)^2 + \left( -\frac{W_{\frac{dh}{dt}}}{\frac{dh}{dt}} \right)^2 \right]^{1/2} \end{aligned}$$

which gives  $Q = (23 \pm 1) \times 10^{-7} \text{ m}^3/\text{sec} \text{ (4.4\%)}$

## (15) Average Velocity (V)

$$V = \frac{4Q}{\pi d^2}$$

Where  $Q = (23 \pm 1) \times 10^{-7} \text{ m}^3/\text{sec}$

$$d = (1.42 \pm 0.02) \times 10^{-3} \text{ m}$$

also

$$\begin{aligned} W_V &= \left[ \left( \frac{\partial V}{\partial Q} W_Q \right)^2 + \left( \frac{\partial V}{\partial d} W_d \right)^2 \right]^{1/2} \\ &= V \times \left[ \left( \frac{W_Q}{Q} \right)^2 + \left( -\frac{2W_d}{d} \right)^2 \right]^{1/2} \end{aligned}$$

which gives  $V = (1.45 \pm 0.075) \text{ m/s} \text{ (}\pm 5.2\%)$

## (16) Reynolds Number (Re)

$$Re = \frac{Vd\rho}{\eta}$$

where

$$V = (1.45 \pm 0.075) \text{ m/s } (\pm 5.2\%)$$

$$d = (1.42 \pm 0.02) \times 10^{-3} \text{ m}$$

$$\rho = (998 \pm 16) \text{ kg/m}^3$$

$$\eta = (2.67 \pm 0.17) \times 10^{-3} \text{ Pa Sec}$$

also

$$\begin{aligned} W_{Re} &= \left[ \left( \frac{\partial Re}{\partial d} W_d \right)^2 + \left( \frac{\partial Re}{\partial V} W_V \right)^2 \right. \\ &\quad \left. + \left( \frac{\partial Re}{\partial \rho} W_\rho \right)^2 + \left( \frac{\partial Re}{\partial \eta} W_\eta \right)^2 \right]^{1/2} \\ &= Re \left[ \left( \frac{W_V}{V} \right)^2 + \left( \frac{W_d}{d} \right)^2 + \left( \frac{W_\rho}{\rho} \right)^2 \right. \\ &\quad \left. + \left( - \frac{W_\eta}{\eta} \right)^2 \right]^{1/2} \end{aligned}$$

which gives

$$Re = 771 \pm 65 \quad (\pm 8.4\%)$$

(17) Apparent Viscosity obtained from the Rotary Viscometer (Table 3;  $\dot{\gamma} = 487.0$ )

$$\text{We have } \eta = \frac{\tau}{\dot{\gamma}} = \frac{(\tau\%)K}{\dot{\gamma}}$$

where

$$\tau\% = 13.6 \pm 1$$

$$K = 0.2239 \pm 0$$

$$\dot{\gamma} = 487.0 \pm 0 \text{ sec}^{-1}$$

Here K is a calibration constant supplied for the particular measurement system used.

$$W_{\eta} = \left[ \frac{\eta}{\tau\%} \cdot W_{\tau\%} \right]$$

which gives

$$\eta = (6.3 \pm 0.5) \times 10^{-3} \text{ PaS } (\pm 7.4\%)$$

VITA AUCTORIS

- 1958 Born in Kurichi, Coimbatore, India on May 21.
- 1974 Completed high school at St. Michael's High School, Coimbatore, India in May.
- 1975 Completed Preuniversity course at P.S.G. College of Arts and Sciences, Coimbatore, India in May.
- 1980 Received the Degree of Bachelor of Engineering (Honours) in Mechanical Engineering from University of Madras (P.S.G. College of Technology), India in June.
- 1982 Currently a candidate for the Degree of Master of Applied Science in Mechanical Engineering at the University of Windsor, Windsor, Ontario, Canada.
